

Lesson 58 Practice: Answers and Rationales

JKSSB Computer Awareness

October 8, 2026

Provenance: All 20 items are original JKSSB-pattern questions (*[Original]*); none reproduces an official paper item.

- Q1. A.** ISP is Internet Service Provider. B, C, and D rearrange the same words into forms the exam never uses.
- Q2. C.** The bit is the smallest unit of data; 8 bits make a byte. A byte (A), a nibble (B), and a word (D) are all larger.
- Q3. C.** F5 starts the slide show from the beginning; Shift+F5 starts from the current slide. F7 (A) is spell check, F9 (B) and F1 (D) have other roles.
- Q4. B.** A formula must start with the equals sign. A leading plus (A), percent (C), or hash (D) does not begin a formula.
- Q5. C.** MICR reads magnetic ink characters. OCR (A) reads printed text, OMR (B) reads marks, and a QR code (D) is a printed matrix symbol.
- Q6. C.** ICs arrived in the third generation; microprocessors arrived in the fourth. A, B, and D name the wrong generations.
- Q7. A.** Android is the open-source mobile operating system. B describes a proprietary system, C a shareware trial, and D a firmware loader — none is the open-source mobile OS.
- Q8. B.** The BIOS initialises hardware and loads the operating system. A device driver (A) is software serving one device, a compiler (C) translates code, and a spreadsheet (D) is an application.
- Q9. B.** The at-sign separates the user name and the domain name. A swaps in host wording, C invents sender/recipient parts, and D names message fields.
- Q10. D.** A Select query retrieves data on a condition without changing records. Update (A), Append (B), and Delete (C) all modify stored data.
- Q11. C.** Cache is not a permanent backup; it holds copies of data that live in RAM. Holding recent data (A), being faster than RAM (B), and exploiting locality (D) are all true.
- Q12. B.** RAM is volatile and ROM is non-volatile. A reverses the pair; C misclassifies both as storage levels; D replaces the volatility distinction with unrelated terms.
- Q13. C.** MICR reads magnetic ink characters, so this pairing is correct. A mislabels the plotter (output) as input; B mislabels the scanner (input) as output; D mislabels the sound card (output) as input.

- Q14. B.** Statements I and II are correct: registers are fastest, and cache is faster than main memory. III is false because RAM is volatile. A omits II; C includes false III and omits I; D includes false III.
- Q15. C.** A digital signature provides authenticity and integrity, while encryption provides confidentiality. A swaps in the encryption role; B reverses both roles; D claims they are the same process.
- Q16. B.** POP3 downloads mail to the local machine while IMAP keeps mail synced on the server. A reverses the pair; C invents a printer role; D confuses mail protocols with a browser.
- Q17. B.** Both statements are true: IPv6 uses 128-bit addresses, and HTTP/3 runs over QUIC rather than TCP. But the reason does not explain the assertion, so the “explains” option (A) is wrong; C and D misjudge one statement as false.
- Q18. B.** Blank and non-numeric input must be traced branch by branch, because the result depends on how the test treats the blank. A over-generalises blank handling; C claims empty cells are never accepted; D confuses the leading equals sign with branch logic.
- Q19. A.** Diagnose the stated bottleneck — multithreading, memory use, or disk activity of that program — since other programs run normally. B blames the clock without evidence; C and D name components that do not set execution speed.
- Q20. B.** COUNTIFS with range–criterion pairs counts rows where all conditions hold. A counts with no criteria; C sums without conditions; D averages without criteria.
